

RepAdapt (Steps 07-09)

This one is much more straightforward than part 1 I think and also slightly better written (if I say so myself haha). Before running we need a `bammap.txt` and a `ploidymap.txt`. If all samples are diploid (which in our cases they are) we could skip the latter but I included it anyway:

```
# to create bammap.txt

ls -1 \
  /rds/project/rds-
fT31urweTx0/projects/project_altitude_ConvergentEvolution/{species}/06_bam
_files/*.realigned.bam \
  > /rds/project/rds-
fT31urweTx0/projects/project_altitude_ConvergentEvolution/{species}/02_inf
o_files/bammap.txt

# to create ploidymap.txt

awk -F'\t' 'NR>1 {print $1 "\t2"}' \
  02_info_files/datatable.txt \
  > 02_info_files/ploidymap.txt
```

the above will be stored in `02_info_files`. To run (from `01_scripts`):

```
nohup nice snakemake --snakefile vcf.smk --profile slurm --config
species={species} --jobs 100 --rerun-incomplete --keep-going --
latency-wait 60 > vcf_{species}.log 2>&1 &
```

`mpileup` is parallelised per scaffold and each job takes anywhere between 10 seconds and 6 hours. so far I haven't had anything run over that but I have kept the wallclock time as 10 hours just in case. Worth saying also that it can easily be done on SL3 so that's what I'm doing.
